shown, 4340 steel has high hardenability, maintaining a higher hardness even an inch away from the quench. This indicates that martensite formation is prevalent and will happen Figure 2. 7 - Hardenability of steel - California State University ... High hardenability is not always desirable in steel, particularly if it is to be welded during fabrication. Apart from the difficulties introduced by alloying (Section 12.7) the operation of heating the metal adjacent to the weld can give rise to the formation of martensite on cooling to room temperature.

Hardenability is, therefore, of the greatest importance, and one must aim for the appropriate concentrations of alloying element needed to harden fully the section of steel under consideration. Equally, there is a little point in using too high a concentration of alloying element, i.e. more than that necessary for full hardening of the required ...

Hardenability is sharply increased by manganese (most potent except boron), chromium, molybdenum and very small additions of boron (0.003 – 0.005%). Nickel and silicon have smaller effects. The hardenability is specially increased, when several alloying elements are added to steel (instead of one in large amount).

7. Hardenability Bands: A steel producer cannot commercially produce steel of exact given composition, and thus a composition range is specified while ordering to the producer. He produces a steel of one exact composition falling within the range of specification.

The hardenability of a metal alloy is the depth to which a material is hardened after putting it through a heat treatment process. It should not be confused with hardness, which is a measure of a sample's resistance to indentation or scratching. It is an important property for welding, since it is inversely proportional to weldability, that is, the ease of welding a material.

Example • Calculate the approximate hardenability of an 8630 (0.3%C, 0.3%Si, 0.7%Mn, 0.5%Cr, 0.6%Ni, 0.2%Mo) alloy steel with an ASTM grain size of 7 70. Solution • Find out base DI for 0.3% carbon • Calculate multiplying factors for each element • Ideal critical diameter found by multiplying base diameter by the multiplying factors

The hardenability of steel depends mainly on its chemical composition, especially the alloying elements and grain size, which increase the hardenability, the heating temperature and the holding time. The steel with good hardenability can obtain uniform and uniform mechanical properties of the whole section of the steel and quenching agent with small quenching stress of steel parts to reduce deformation and cracking.

Rather, hardenability is how deep a steel alloy can be hardened. Steels that deeply harden are called high hardenability steels, while steels that do not harden deeply are called low hardenability steels. The major factors affecting hardenability and the rate of austenite transformation are carbon content, grain size, and alloying elements.

The larger the ideal diameter, the higher the hardenability of the steel. The ideal diameter of a plain carbon steel with carbon content of 0.4% (1040 steel) and whose ASTM grain size number is 7 is 5.5 mm (0.215 inches). The ideal diameter for a 4340 steel (0.8 Cr, 1.75 Ni, 0.25 Mo) is over. 150 mm (6 inches).

Figure 4: Influence of steel hardenability on the change in overall diameter of carburized 110 mm diameter 2.8 module spur gears. Gears were carburized at 920 ° C and quenched in 90 ° C oil [6]. In one study [7], a customer was looking to increase performance of an automotive pinion gear by changing alloy from AISI 8620 to AISI 4320.
